

The Deployment Process

A. Sinan Unur

November 30, 2018

Deployment Steps

\$ rake dev:up

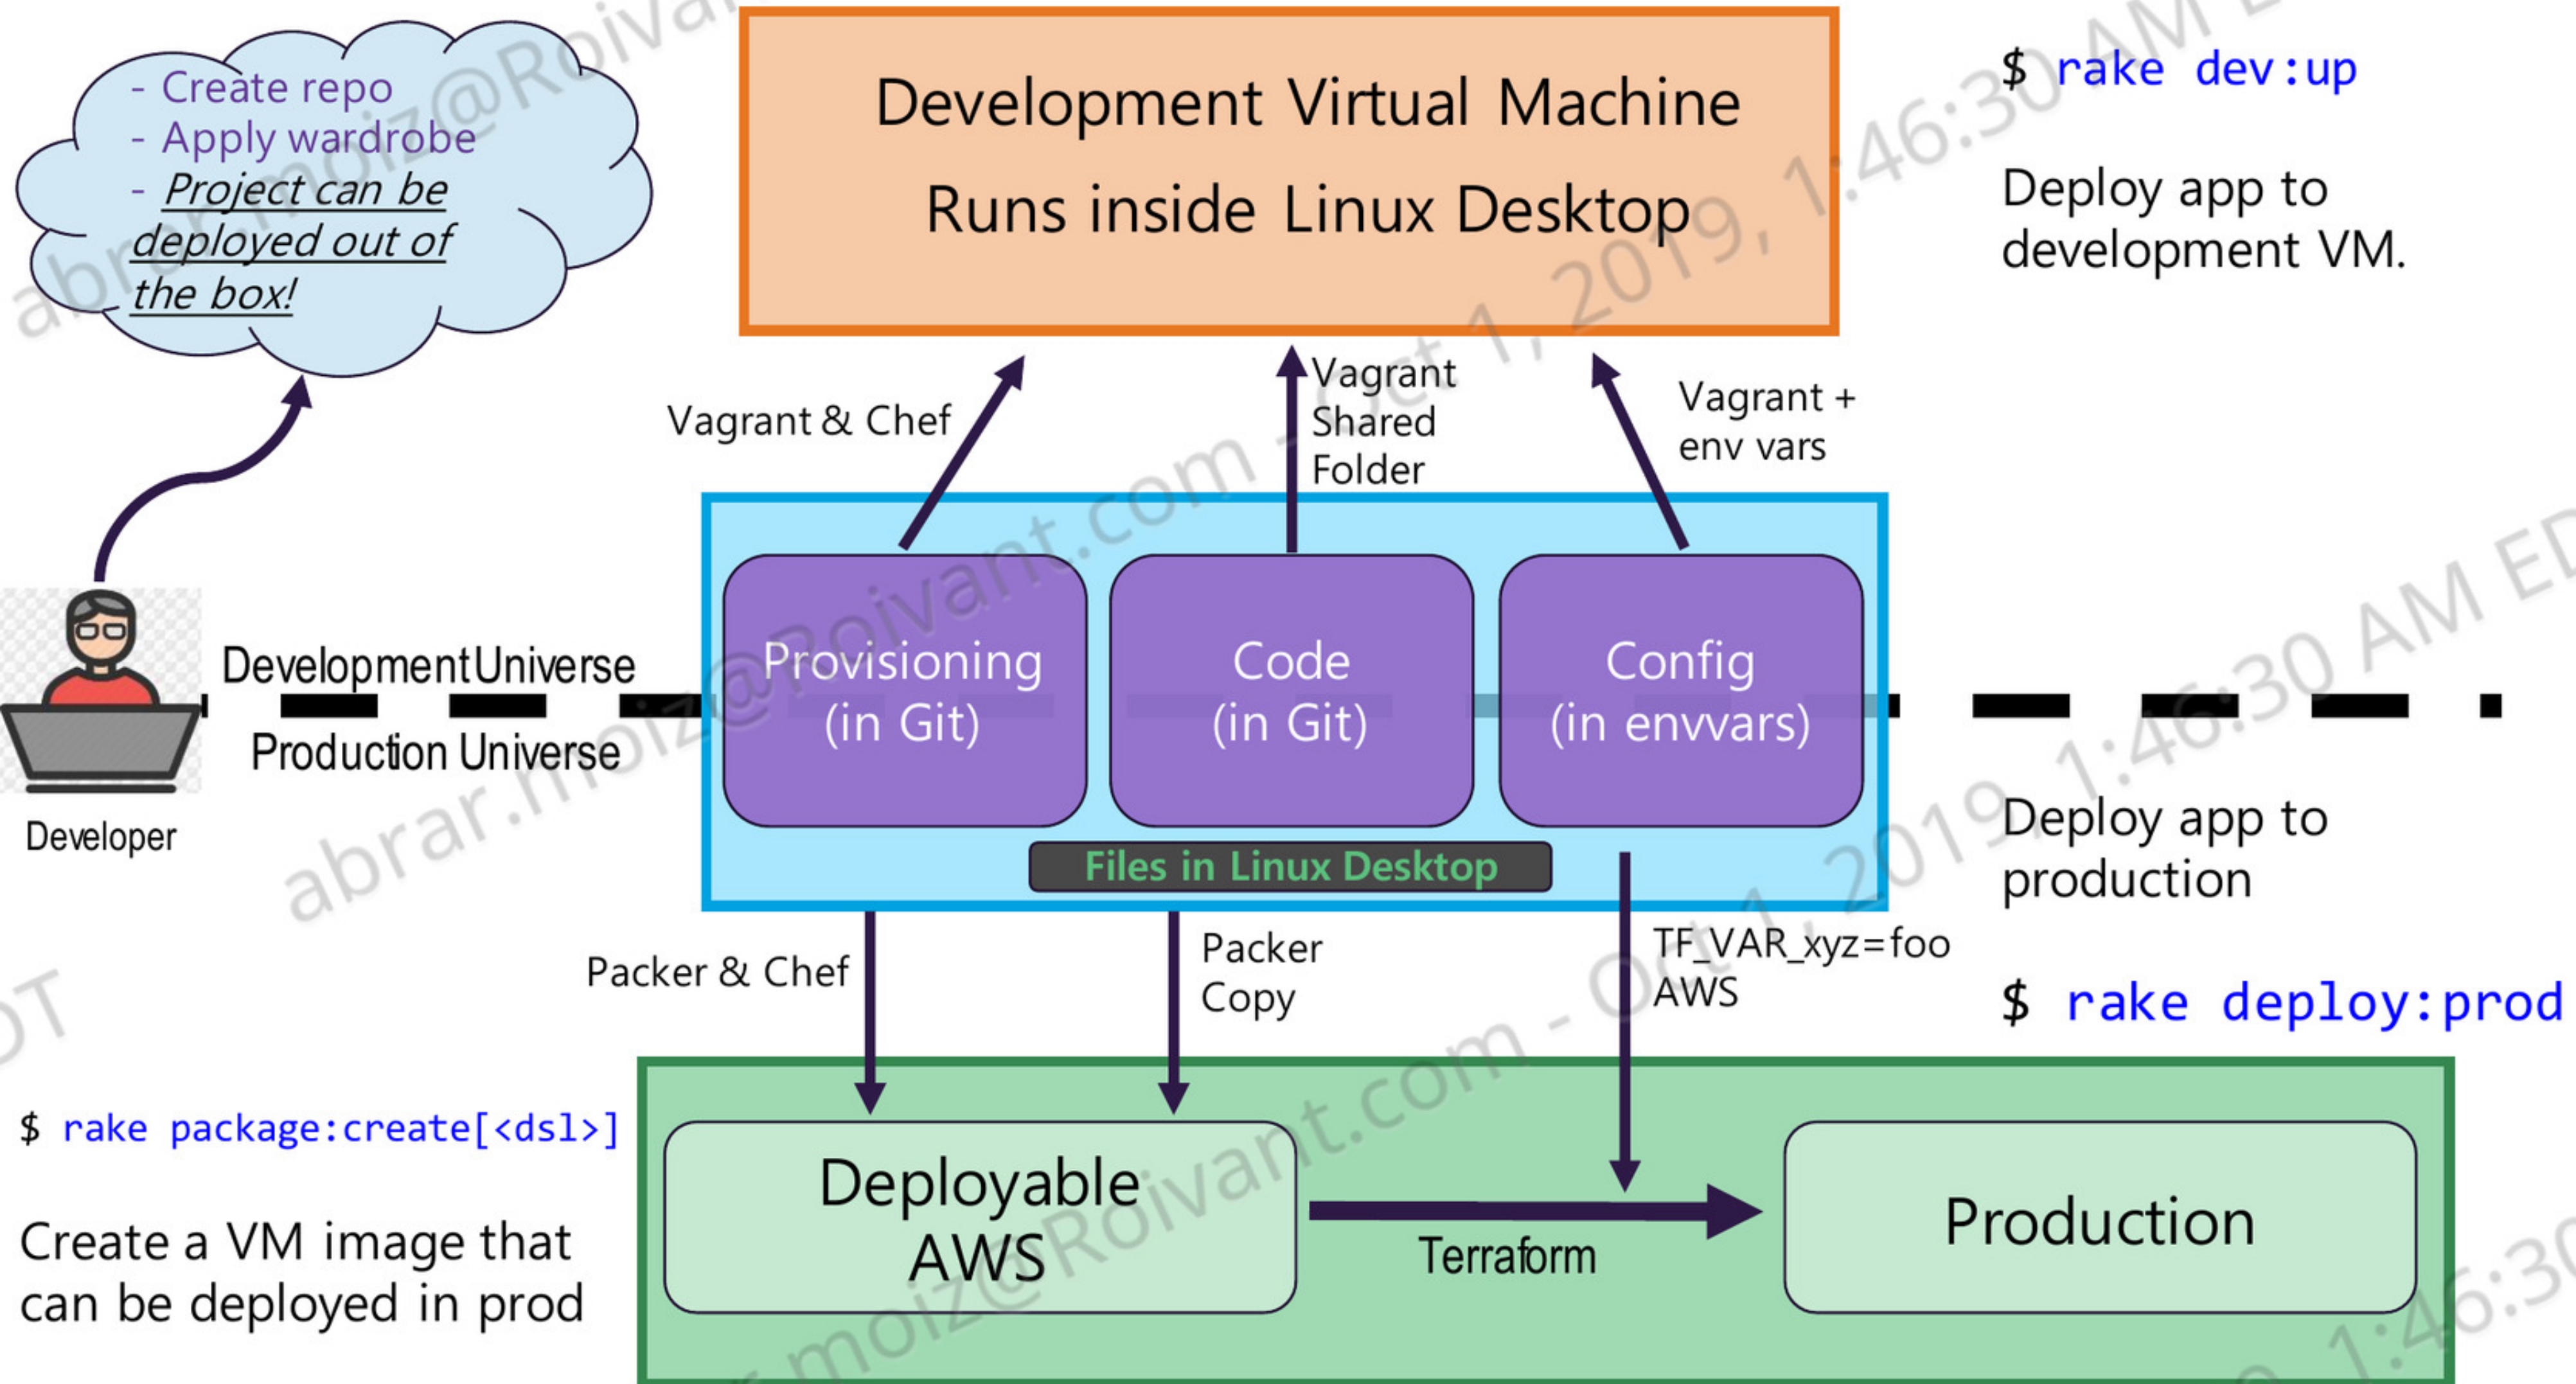

\$ rake test:all

\$ rake package:create[<ds1>]

\$ rake deploy:prod

Any questions?

Bird's eye view

Start a project

- Create a repo for project
- Clone it in Linux Desktop, apply wardrobe to it
 - This provides all the supporting structure
- App is deployable the moment wardrobe is applied

Deploy to development

- \$ **rake dev:up** in Linux Desktop deploys app to development VM
- Vagrant sets up the development VM
- Project directory mapped under /vagrant in development VM
- Chef sets up development environment (libraries, middleware etc)
- Use **rake dev:shell** to open a shell to your development VM

Constructing development VM

- Provisioned through Chef recipes under app directory in Linux Desktop and tracked using Git
- Your code is in app directory in Linux desktop, tracked using Git
- Configuration details is set via envvars
- Development environment settings geared towards that. E.g. live code reloading, working directory ...

Deployment to production

- Keep in mind, every `rake dev:up` is a deployment of your app to the development environment
- Deploying to production takes the same structure, changes the values of some settings and variables, and creates an image suitable for a production environment
- In essence, this is no different than deploying to development.

Deployment to production

- Packer and Chef are used to create an image suitable for being run in the “cloud” using the *same* structure as when your app is deployed to development VM

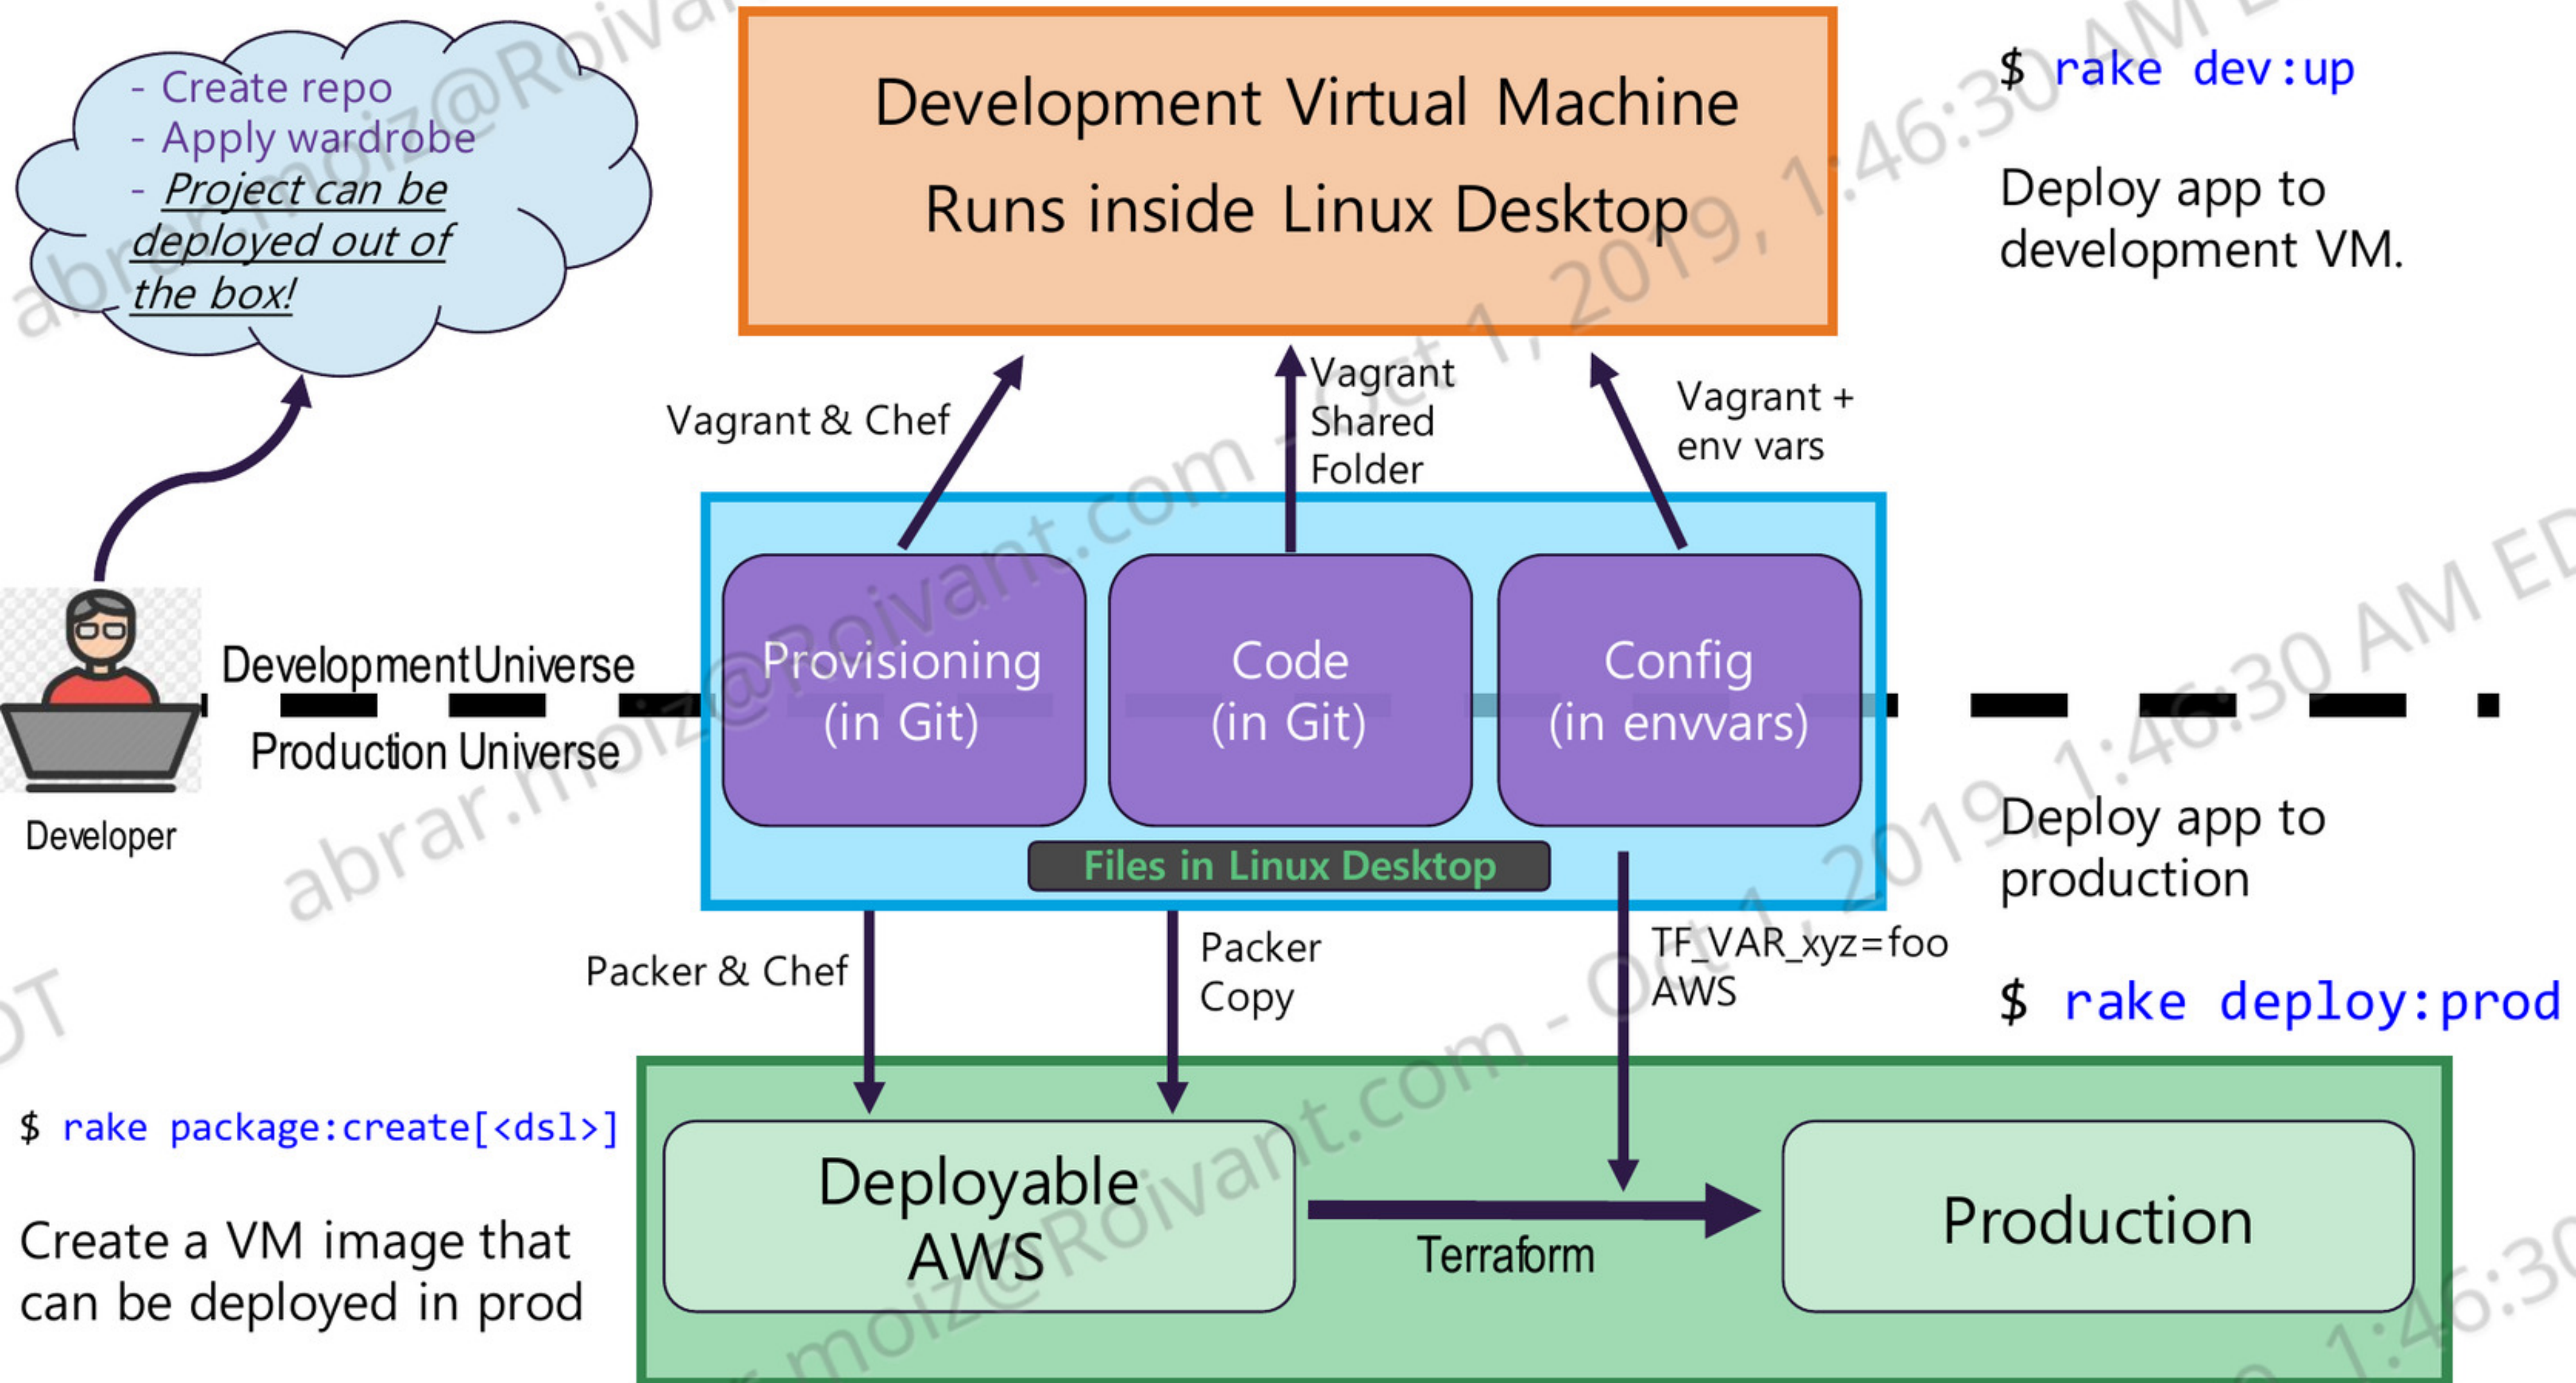

```
$ rake package:create[<ds1>]
```

- Packer copy puts that image on AWS
- Terraform injects configuration into an image to deploy a VM that is fit for purpose.

Summary

- \$ **rake dev:up** is deployment for development
- Deployment to development *is* deployment
- \$ **rake deploy:prod** is deployment for users
- Development VM is a structural clone of production VM
